1. RESOURCES FILE

1.1. PRESENTATION

The electric power steering system simulated by EXXOtest’s MT-DAE model is currently fitted to several vehicles, notably the Citroen C3. The assistance provided by this system varies as a function of road speed.

Unlike hydraulic power steering systems, power is only consumed when assistance is demanded: i.e. when the driver turns the steering wheel. This results in a power saving compared with hydraulic power steering systems. No direct interaction with the vehicle’s engine is required since the electric power steering draws current from the alternator (when the engine is running).

Moreover, this system eliminates any risks associated with leaking hydraulic hoses and offers greater reliability since the mechanisms used are simpler. The basic mechanics of the system are essentially the same as for traditional steering (rack-and-pinion system).

1.2. OVERVIEW OF SYSTEM OPERATION

Amplifier, depending on the speed and torque on the steering wheel, actions on steering tie-rods

N_engine
Contact (+APC)

Action on steering wheel

Electrical energy
1.2.1. Principle of operation

- When the driver turns the steering wheel, electric power steering provides an assistive torque to help to steer the wheels.
- This assistive torque is provided by an electric motor. The torque is applied to the rack-and-pinion system via a motor and reducing gear assembly. It supplements the torque applied by the driver to the steering wheel.
- The force exerted by the driver on the steering wheel is transmitted to the steering rack. This input torque is measured by a torque sensor and a corresponding electrical signal is generated and sent to the electric power steering (EPS) control unit.
- The electric motor is called the steering assistance motor. The power which the control unit requests to drive the motor is dependent on two variables: the torque applied to the steering wheel and the vehicle’s speed.

<table>

</tr>
<tr>
<td>Speed greater than 152 km/h</td>
<td>Small, almost zero</td>
<td>The assistance motor is no longer supplied with power and is disengaged from the steering column.</td>
</tr>
</tbody>
</table>
1.2.2. Component elements

The electric power steering system consists of a conventional manual steering system fitted with the following:

1. Torque sensor
2. Steering assistance motor
3. Power supply connector for assistance motor
4. Signal from torque sensor connector

1.3. DESCRIPTION OF THE COMPONENTS

1.3.1. Torque sensor

The torque sensor continuously measures the torque which the driver applies to the steering wheel. The torque sensor detects and measures: the direction of rotation of the steering wheel and the torque applied by the driver.

The electronics integrated into the EPS control unit prevents any assistance torque being provided in a direction which opposes the direction of rotation of the steering wheel and disables all assistance when there is no input on the steering wheel.

This steering system does not require input from a steering wheel angle sensor.

Mounting position

The torque sensor is mounted on the pinion shaft, between the input shaft (steering column and steering wheel side) and the output shaft (rack-and-pinion side)
Description

A: Rack-and-pinion side

B: Steering wheel side

1: Measuring coil which whose position is fixed in relation to the steering column
2: Reference measuring coil whose position is fixed in relation to the steering column
3: Input shaft on steering wheel side
4: Torsion bar between the input and output shafts
5 and 6: Detection collar forming one piece with the input shaft
7: Detection ring forming one piece with the output shaft
8: Output shaft on rack side

This sensor is an eddy current torque meter which measures the angle of twist. A series of notches around the periphery of each detection collar are arranged such that, when torsion is applied, the notches shift position in relation to each other.

The effect of this shift in notch position between adjoining collars is to change the inductance in the two coils.

The signal processing electronics are located near to the coils.
The torsion sensor has three subassemblies:

- The mechanical subassembly consists of a torsion bar. The angular shift between the input shaft and the output shaft is proportional to the torque applied by the driver. The limit of this angular offset is \( \pm 4.5^\circ \).

- The electromagnetic components provide information about the angular deviation of the detection collars (component 7 in the diagram compared with component 6) and consequently of the input shaft compared with the output shaft.

- The sensor's electronics which transform this angular position information into torque information based on the principle that the angular deformation of the torsion bar is proportional to the steering torque.

The torque sensor has a second detection stage. A reference coil, whose inductance is not changed by the angular deviation of the first set of detection collars. It sends a reference electrical signal, irrespective of the environmental conditions (e.g. temperature).

![Graph showing the signal sent by the torque sensor to the control unit](image-url)
ACTUATION WHICH PRODUCED THE ABOVE SIGNAL

Start with the steering wheel in its straight-ahead position, then rotate for a right turn to full lock, then rotate for a left turn to full lock then return to the straight-ahead position.
1.3.2. Vehicle speed sensor

On some versions of the electric power steering system, a speed sensor provides the control unit with information about the vehicle’s speed.

If the vehicle is fitted with ABS, this information is transmitted directly by this system on the multiplexed bus (there is no speed sensor).

**Function**

*It is a Hall-effect sensor. It produces 5 signal “spikes” per meter and 8 signal “spikes” per rotation. The vehicle speed sensor provides an electrical signal whose frequency is proportional to the speed of rotation of the gearbox’s secondary shaft, thus to the vehicle’s speed. It is mounted on the gearbox.*

**The Hall effect**

The key component of this system is an extremely thin, 1.2-mm square plate through which a current passes from point A to point B.

When a magnetic field SN is applied perpendicular to the plate, a very weak Hall voltage (0.001 V) can be measured between points E and F. This voltage is generated as a result of the current lines A B being deviated by the magnetic field. No voltage is measured if the magnetic field is absent.

**How the sensor works**

When the pole wheel (made up of successive segments of north and south poles) rotates, a series of north and south poles pass in front of the Hall plate. The voltage generated across the plate thus alternates as the current direction changes with each new pole.

The sensor’s integrated circuit amplifies the square-wave signal produced, whose high value corresponds to one current direction across the plate and whose low value corresponds to the reverse direction of current through the plate, induced by the polarity of the pole passing in front of it.
Example of the signal produced by the sensor

This is the signal received by the injection & ignition control unit; it is measured at terminal 3 of the vehicle speed sensor's connector.

1.3.3. Motor and reducing gear assembly

<table>
<thead>
<tr>
<th>Designation</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Assistance motor</td>

</tr>
<tr>
<td>4</td>
<td>Reducing gear assy</td>
</tr>
<tr>
<td>5</td>
<td>To steering wheel</td>
</tr>
<tr>
<td>6</td>
<td>Output shaft</td>
</tr>
</tbody>
</table>
Internal view of the assembly

The reducing gear consists of a worm wheel and a worm screw.
- The worm wheel forms one piece with the steering column
- The worm screw is driven by the steering assistance motor’s shaft

The reducing gear ratio is: 1/15

The steering assistance motor is a brushed d.c. motor.
There are two types of electric motor, differentiated by their power:
- 60 amperes for light vehicles
- 65 amperes for heavier vehicles fitted, for example, with an option such as air conditioning or an automatic transmission

The motor cannot operate unless:
- The battery's voltage is 9 V or higher.
- The engine speed is faster than 285 rpm

**Thermal protection**

The control unit gradually cuts back on the assistance (by reducing the maximum current) if the vehicle is steered heavily for a long period (e.g. turning from one full-lock position to the other several times in a row) to stop the assistance motor overheating and to avoid any risk of damaging or degrading the motor or control unit.
The current is gradually restored as the system cools.
The power interface is controlled by a voltage chopper which regulates the mean value of the current which the motor can draw.
1.3.4. Electric power steering (EPS) control unit

The EPS control unit is fitted in the engine compartment.

E.g. for a Citroen C3:

![EPS control unit diagram]

3 – Injection & ignition control unit
4 – EPS control unit
5 – Fuse box in engine compartment (BSM)
6 – Battery compartment

The EPS control unit is connected via 3 cable harnesses:

![Cable harness diagram]

7 – Power supply for steering assistance motor: 2-channel connector
8 – Power supply for EPS control unit from the battery: 2-channel connector
9 – 9-channel connector, comprising: 4 wires carrying information from the torque sensor, 1 wire carrying the system temperature signal, 2 twisted wires (CAN bus), 1 wire for +APC and the diagnostics line.
1.3.5. Degraded modes

The EPS control unit is set up with a strategy for managing system failures:

- Within the steering system (torque sensor fault, loss of an electric circuit)
- External to the steering system (incorrect CAN communication, invalid vehicle speed information)

The EPS control unit switches to degraded mode if one or more fault codes are generated.

There are two degraded modes:

- Baseline assistance (assistance greatly reduced)
- Total loss of assistance

<table>

2. USER FILE

2.1. INTENDED USE

This equipment has been designed to let trainees learn about the operation of an electric power steering system developed by the PSA PEUGEOT CITROEN group.

It shows how the equipment is put together, presents a number of components used on production vehicles and lets the trainee access the messages exchanged between the control unit, sensors and actuators.

It can also show how the system behaves when faults occur. The range of diagnostic possibilities is thus very broad.

2.2. USING THE MODEL

2.2.1. Initial state

Position the model in a clear area within the workshop, reasonably close to an electrical power outlet.

Apply the brake to each of the 4 casters

Plug the power cable into a 230 V mains supply

The components are supplied with power by a battery which is permanently connected to a charger which is in turn connected to the mains (230 V); this arrangement maintains a constant nominal voltage even during prolonged use.
2.2.2. Switching on

The model is switched on using the red key. The power steering is only active when the engine is running. To simulate the + DEM information (engine running) press on the switch (4) to start up the engine.

2.2.3. Composition

All the relevant elements present on the vehicle are provided on the model.

Returning to the model, plug its power cable into the mains (in accordance with the safety instructions detailed in the resources file) and screw down the handle on the mechanical resistance so that the force applied by the rack is 330 DaN.

6. **For a vehicle speed of 0 km/h, what force must be applied by the "driver"?**

7. **And similarly for a speed of 100 km/h?**

8. **And for 180 km/h?**

9. **What do you notice?**

10. **To draw together the various points of this first PE, explain how electric power steering works.**
3.1.3. Summary

1. Presentation

The electric power steering (EPS) system provides speed-dependent, electric-powered assistance to the driver when steering. This type of power steering system offers many benefits:

- A much improved driving experience in both urban and extra-urban environments.
- A non-negligible reduction in fuel consumption of about 0.2 litres per 100 km.
- No requirement for hydraulic fluids for the assistance pump or for hoses to carry the fluids.

2. Principle of operation

When the driver turns the steering wheel, electric power steering provides an assistive torque to help to steer the wheels.

The assistance torque is provided by an electric motor which supplements the torque transmitted from the steering wheel applied by the driver. This driver-induced torque is measured by the torque sensor and sent to the EPS control unit.

The control unit supplies the motor with power as a function of:
- The torque applied to the steering wheel
- The vehicle’s speed.

3. Components

The electric power steering system consists of a conventional manual steering system fitted with the following:

- A torque sensor
- An electric assistance motor and its reducing gear
- Two cable harnesses (a signal harness and a power harness)
- A control unit connected to the CAN bus (not shown in the drawing)

<table>

</tbody>
</table>
4. **Component elements**

   a) Torque sensor
   
   The torque sensor continuously measures the torque which the driver applies to the steering wheel.

   b) Vehicle speed sensor
   
   It provides the electric power steering control unit with information about the vehicle’s current speed.

   ![Torque Sensor](image1)

   c) Motor and reducing gear assembly
   
   Consists of an electric steering assistance motor coupled to a reducing gear which are linked to the steering rack (the reducing gear multiplies up the force generated by the motor).

   ![Motor and Reducing Gear Assembly](image2)

   The motor cannot operate unless:
   
   - The battery's voltage is 9 V or higher.
   - The engine speed is faster than 285 rpm

**Thermal protection** The control unit gradually cuts back on the assistance (by reducing the maximum current) if the vehicle is steered heavily for a long period (e.g. turning from one full-lock position to the other several times in a row) to stop the assistance motor overheating and to avoid any risk of damaging or degrading the motor or control unit. The current is gradually restored as the system cools.
d) Electric power steering (EPS) control unit

The EPS control unit receives information from:

- the torque sensor
- the speed sensor
- the temperature sensor

It controls the operation of the electrical motor based on these parameters.
3.2. PRACTICAL EXERCISE No. 2

3.2.1. Meaning of the symbols

- **CAUTION!** This symbol draws attention to an important point.

- When you see this symbol, you must ask the trainer to watch or supervise in person the tasks indicated.

- When you see this symbol, your response to the questions must involve highlighting with different colours or drawing.

- When you see this symbol, you must complete a table or perform calculations.
3.2.2. Preparatory work

By referring to the exercise file, prepare the workstation in accordance with the instructions relating to safety.

☞ Call the trainer

1. By referring to the wiring diagram and to the resources file, indicate the function of each element

<table>

2. **Recording the signal produced by the torque sensor**

By referring to the wiring diagram and the channel assignation table (in the resources file): Identify the torque sensor by drawing a circle around it and then highlight:

- In green, the output signal from the torque sensor
- In red, the power supply
- In blue, its ground

Call the trainer

Connect the multimeter to measure the signal.

3. **Record from the model the output voltage from the torque sensor and its physical value shown on the display. Using this data, complete the table below.**

<table>
<thead>
<tr>
<th>Action performed on the EPS model</th>
<th>Sensor output voltage</th>
<th>Torque on steering wheel</th>
</tr>
</thead>
<tbody>
<tr>
<td>Apply force to the steering wheel at its full right-lock position</td>
<td>3.83</td>
<td>10.5</td>
</tr>
<tr>
<td>Do not apply any force to the steering wheel</td>
<td>2.48</td>
<td>0</td>
</tr>
<tr>
<td>Apply force to the steering wheel at its full left-lock position</td>
<td>1.13</td>
<td>-10.8</td>
</tr>
</tbody>
</table>
Complete the graph below with the values recorded above.

![Graph](image)

What can you say about the operation of the torque sensor based on the data you recorded?

The plot is a straight line; this indicates that the sensor’s output voltage is proportional to the torque applied to the steering wheel.
If no force is applied to the steering wheel, the output voltage is stable at 2.5 V; this voltage increases if you turn the steering wheel to the right and reduces if you turn it to the left.
3.2.4. Summary

Refer to page 27, PE No. 1
3.3. PRACTICAL EXERCISE No. 3

3.3.1. Meaning of the symbols

CAUTION! This symbol draws attention to an important point.

When you see this symbol, you must ask the trainer to watch or supervise in person the tasks indicated.

When you see this symbol, your response to the questions must involve highlighting with different colours or drawing.

When you see this symbol, you must complete a table or perform calculations.
Information: “the customer complains that the steering has become too stiff”

1. **Identify the vehicle’s characteristics**

<table>
<thead>
<tr>
<th>Make of vehicle</th>
<th>Registration No.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Model</td>
<td>Engine power</td>
</tr>
<tr>
<td>Date of first registration</td>
<td>Fuel used</td>
</tr>
<tr>
<td>Serial No.</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Fuel level</th>
<th>Kilometrage</th>
<th>Audio system YES/NO</th>
<th>Date received for work</th>
</tr>
</thead>
<tbody>
<tr>
<td>0 1/4 1/3 1/2 1</td>
<td>[ ] [ ] [ ] [ ]</td>
<td>[ ]</td>
<td>[ ]</td>
</tr>
</tbody>
</table>

2. **Describe the symptoms observed**

- The diagnostic light for Power steering is lit
- The EPS system no longer delivers a comfortable driving experience

3. **Study the diagrams needed for the diagnosis**

   - Schematic diagram
   - Layout diagram
   - Summary of the system

4. **Study the functioning of the circuit suspected to be at fault**

   **Method**
   - Identify the elements on the diagram.
   - Highlight the power supplies (in red) and the grounds (in black) for the electronic control unit
   - Highlight in blue the information from any sensors
   - Indicate (with a pencil) the current flow when the driver actuates the system.

*Monsieur !

☞ Call the trainer

*(Explain the operation of the circuit)*
5. **What do you think may have caused the malfunction (list all the possible causes)**

- Torque sensor.
- Vehicle Speed Information.
- Temperature sensor on the EPS unit
- Speed sensors mounted on the gearbox.
- Management of the EPS control unit
- Interconnections with the injection & ignition and/or ABS control units

(Call the trainer)

6. **Use the equipment which assists in forming a diagnosis**

**Method:**

- Locate the vehicle’s diagnostic connector
- Connect up the diagnostic station*
- Configure the station
- Follow the procedure specified for the diagnostic tool

7. **Interrogate the control unit suspected of being at fault to check for any stored faults and interpret them**

<table>
<thead>
<tr>
<th>Fault code Ref.</th>
<th>Name of the Component or Circuit</th>
<th>Reading of the faults observed</th>
</tr>
</thead>
<tbody>
<tr>
<td>CAN bus fault</td>
<td>Torque sensors</td>
<td>Torque sensor fault</td>
</tr>
</tbody>
</table>

(Call the trainer)
8. Checking the elements suspected of being at fault

![Diagram of Electronic Control Unit and System's Wiring Harness]

<table>
<thead>
<tr>
<th>Component to be checked</th>
<th>Channel No. on terminal board</th>
<th>Measurement conditions, ignition key set to “On” or “Off”</th>
<th>Expected value</th>
<th>Recorded value</th>
<th>Ok/Not Ok</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Continuity 1</strong></td>
<td></td>
<td>Engine not running Ignition set to “Off”</td>
<td>Audible signal</td>
<td>signal</td>

</tr>
<tr>
<td>Torque sensor ground</td>
<td></td>
<td>Engine switched off Ignition set to “Off”</td>
<td>Audible signal</td>
<td>No signal</td>
<td><strong>Not OK</strong></td>
</tr>
</tbody>
</table>

(Call the trainer)
8. **What maintenance operations should be performed to fix the system?**

   Repair or replace the cable loom connected to the power steering torque sensor (wire 6783 BA)

9. **What is the point of clearing the faults? (tick the correct answer)**

   - [ ] There is no point
   - [ ] To make the system work better
   - [ ] To re-initialise the control unit

10. **Report**

    Present and explain the work to the customer

    | Fault investigation
    | Reading the diagnostics
    | Repair/replacement of the torque sensor’s cable harness
    | Clearing of the faults
3.3.2. Summary

Using a Terminal Board

To confirm or complete the diagnostic performed by the checking tools, measurements should be made directly on the circuit which serves the defective components.

Using the terminal board, the various possible electrical checks are:

- Connector 1 only is connected
- Connectors 1 & 2 are connected
- Resistance of the components
- Continuity of the cable harness
- Power supply voltage of the components
- Recording of the signals transmitted or received by the control unit
DECLARATION OF CONFORMITY

By this declaration of conformity under the terms of Electromagnetic Compatibility Directive 2004/108/EC:

S.A.S. ANNECY ELECTRONIQUE
Parc Altais – 1, rue Callisto
74650 CHAVANOD

Declares that the following product:

I - has been manufactured in accordance with the requirements of the following European directives:

and complies with the requirements of standard:

  Electrical equipment for measurement, control and laboratory use. EMC requirements.

II – has been manufactured in compliance with the requirements of European directives relating to the design of Electrical & Electronic Equipment (EEE) and the management of Waste Electrical & Electronic Equipment (WEEE) in the EU.:

Signed in Annecy, France, on 24 July 2007

Stéphane Sorlin, Chairman
